## Research Focus

My research focuses on using geophysical and geochemical methods to understand planetary habitability, mainly in ocean worlds. I study how oceans influence global thermal evolution and composition, and what this might mean for life. I am interested in geochemical fluxes in ocean worlds, by analogy to biogeochemical fluxes in the Earth system. As a comparative planetologist I develop analytical and numerical models for planetary interiors spanning the entire solar system. My experimental research develops fundamental inputs for those models, collecting thermodynamic equations of state and transport properties for fluids and ices. I use this information to evaluate oceanic heat transport and double diffusive convection in Europa, and to the geophysical constraints imposed by ocean composition on the radial structures of potentially habitable worlds. Increasingly, I use these models to develop model ensembles covering the parameter space of possible geophysical signals—seismic, magnetic, and gravitational—to improve the fidelity of returned science from investigations of composition and habitability.
